Part 1: Mechanisms using a block cipher

### **National foreword**

This British Standard is the UK implementation of ISO/IEC 9797-1:2011+A1:2023. It supersedes BS ISO/IEC 9797-1:2011, which is withdrawn.

The UK participation in its preparation was entrusted to Technical Committee IST/33/2, Cryptography and Security Mechanisms.

A list of organizations represented on this committee can be obtained on request to its committee manager.

#### **Foreword**

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of the joint technical committee is to prepare International Standards. Draft International Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication as an International Standard requires approval by at least 75 % of the national bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO and IEC shall not be held responsible for identifying any or all such patent rights.

ISO/IEC 9797-1 was prepared by Joint Technical Committee ISO/IEC JTC 1, *Information technology*, Subcommittee SC 27, *IT Security techniques*.

This second edition cancels and replaces the first edition (ISO/IEC 9797-1:1999), which has been technically revised. MAC Algorithms 5 and 6 of ISO/IEC 9797-1:1999, which consisted of two single CBC-MAC computations, have been replaced by two other MAC algorithms, which perform single CBC-MAC computations and which offer improved efficiency. Annex A on object identifiers has been added. The security analysis in Annex C has been updated and Annex D on the relationship to previous standards has been added.

ISO/IEC 9797 consists of the following parts, under the general title *Information technology* — *Security techniques* — *Message Authentication Codes (MACs)*:

- Part 1: Mechanisms using a block cipher
- Part 2: Mechanisms using a dedicated hash-function
- Part 3: Mechanisms using a universal hash-function

Further parts may follow.

ISO/IEC 9797-1:2011(E)

#### Introduction

In an IT environment, it is often required that one can verify that electronic data has not been altered in an unauthorized manner and that one can provide assurance that a message has been originated by an entity in possession of the secret key. A MAC (Message Authentication Code) algorithm is a commonly used data integrity mechanism that can satisfy these requirements.

This part of ISO/IEC 9797 specifies six MAC algorithms that are based on an n-bit block cipher. They compute a short string as a function of a secret key and a message of variable length.

The strength of the data integrity mechanism and message authentication mechanism is dependent on the length (in bits)  $k^*$  and secrecy of the key, on the block length (in bits) n and strength of the block cipher, on the length (in bits) m of the MAC, and on the specific mechanism.

The first mechanism specified in this part of ISO/IEC 9797 is commonly known as CBC-MAC (CBC is an abbreviation of Cipher Block Chaining).

The other five mechanisms are variants of CBC-MAC. MAC Algorithms 2, 3, 5 and 6 apply a special transformation at the end of the processing. MAC Algorithm 6 is an optimized variant of MAC Algorithm 2. MAC Algorithm 5 uses the minimum number of encryptions. MAC Algorithm 5 requires only a single block cipher key setup but it needs a longer internal key. MAC Algorithm 4 applies a special transformation at both the beginning and the end of the processing; this algorithm is recommended for use in applications which require that the key length of the MAC algorithm be twice that of the block cipher.

ISO/IEC 9797-1:2011(E)

# Information technology — Security techniques — Message Authentication Codes (MACs) —

#### Part 1:

## Mechanisms using a block cipher

#### Scope

This part of ISO/IEC 9797 specifies six MAC algorithms that use a secret key and an n-bit block cipher to calculate an *m*-bit MAC.

This part of ISO/IEC 9797 can be applied to the security services of any security architecture, process, or application.

Key management mechanisms are outside the scope of this part of ISO/IEC 9797.

This part of ISO/IEC 9797 specifies object identifiers that can be used to identify each mechanism in accordance with ISO/IEC 8825-1. Numerical examples and a security analysis of each of the six specified algorithms are provided, and the relationship of this part of ISO/IEC 9797 to previous standards is explained.

#### **Normative references**

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO/IEC 18033-3, Information technology — Security techniques — Encryption algorithms — Part 3: Block ciphers

#### Terms and definitions

For the purposes of this document, the following terms and definitions apply.

#### 3.1

#### block

bit string of length n

#### block cipher key

key that controls the operation of a block cipher

#### 3.3

#### ciphertext

data which has been transformed to hide its information content

[ISO/IEC 9798-1:2010]

#### ISO/IEC 9797-1:2011(E)

#### 3.4

#### data integrity

property that data has not been altered or destroyed in an unauthorized manner

[ISO 7498-2]

#### 3.5

#### decryption

reversal of a corresponding encryption

[ISO/IEC 9798-1:2010]

#### 3.6

#### encryption

reversible operation by a cryptographic algorithm converting data into ciphertext so as to hide the information content of the data

[ISO/IEC 9798-1:2010]

#### 3.7

#### kev

sequence of symbols that controls the operation of a cryptographic transformation

NOTE Examples are encryption, decryption, cryptographic check function computation, signature generation, or signature verification.

[ISO/IEC 9798-1:2010]

#### 3.8

#### MAC algorithm key

key that controls the operation of a MAC algorithm

#### 3.9

#### **Message Authentication Code**

#### **MAC**

string of bits which is the output of a MAC algorithm

NOTE A MAC is sometimes called a cryptographic check value (see for example ISO 7498-2 [1]).

#### 3.10

#### Message Authentication Code algorithm

#### MAC algorithm

algorithm for computing a function which maps strings of bits and a secret key to fixed-length strings of bits, satisfying the following two properties:

- for any key and any input string, the function can be computed efficiently;
- for any fixed key, and given no prior knowledge of the key, it is computationally infeasible to compute the function value on any new input string, even given knowledge of a set of input strings and corresponding function values, where the value of the ith input string might have been chosen after observing the value of the first i -1 function values (for integers i > 1)
- NOTE 1 A MAC algorithm is sometimes called a cryptographic check function (see for example ISO 7498-2 [1]).
- NOTE 2 Computational feasibility depends on the user's specific security requirements and environment.

#### 3.11

#### *n*-bit block cipher

block cipher with the property that plaintext blocks and ciphertext blocks are n bits in length

[ISO/IEC 10116]

ISO/IEC 9797-1:2011(E)

#### 3.12

#### output transformation

function that is applied at the end of the MAC algorithm, before the truncation operation

#### 3.13

#### plaintext

unencrypted information

NOTE Adapted from ISO/IEC 9798-1:2010.

#### 4 Symbols and notation

Throughout this part of ISO/IEC 9797 the following symbols and notation are used:

 $CT_i$  *n*-bit binary representation of the integer *i*.

D data string to be input to the MAC algorithm.

 $D_i$  block derived from the data string D after the padding and splitting process.

 $d_K(C)$  decryption of the ciphertext C with the block cipher e using the key K.

*e* block cipher used in the MAC algorithm.

 $e_K(P)$  encryption of the plaintext P with the block cipher e using the key K.

*F* final iteration.

g output transformation that maps the block  $H_q$  to the block G.

*G* block that is the result of the output transformation.

 $GF(2^n)$  finite field with exactly  $2^n$  elements.

 $H_0,H_1,\ldots,H_q$  blocks used in the MAC algorithm to store intermediate results.

*k* length (in bits) of the block cipher key.

*k*\* length (in bits) of the MAC algorithm key.

K, K', K'' secret block cipher keys of length (in bits) k.

 $K_1, K_2$  secret masking keys of length (in bits) n.

L length block, used in Padding Method 3, equal to the binary representation of the length of the input message, left-padded to form an *n*-bit block.

 $L_D$  length (in bits) of the data string D.

*m* length (in bits) of the MAC.

 $\operatorname{multx}(T)$  operation on an n-bit string T defined as T\*x, where T is treated as an element in the finite field  $\operatorname{GF}(2^n)$ , and is multiplied by the element corresponding to the monomial x in  $\operatorname{GF}(2^n)$ . It can be computed as follows, where  $T_{n-1}$  denotes the leftmost bit of T and, as defined below, << denotes a one-bit left shift operation.

$$\mathrm{multx}(T) = \begin{cases} T \ll 1 & \text{if } T_{n-1} = 0 \\ (T \ll 1) \oplus \tilde{P}_n & \text{if } T_{n-1} = 1 \end{cases}$$

block length (in bits) of the block cipher.

#### ISO/IEC 9797-1:2011(E)

$p_n(x)$	irreducible poly	unomials of deare	e n  over  GF(2)	that is no	olynomials wit	h no non-trivial divisors.
$p_n(x)$	irreducible por	ynoniais oi acgie	$c n$ over $\operatorname{Gr}(z)$ ,	mat is, p	Orymorniais wii	ii iio iioii-tiiviai divisois.

- $\widetilde{p}_n$  string of bits of length n, consisting of the rightmost n coefficients (corresponding to  $x^{n-1}$ ,  $x^{n-2}$ , ..., x,  $x^0 = 1$ ) of the irreducible polynomial  $p_n(x)$ . For n=128,  $p_n(x) = x^{128} + x^7 + x^2 + x + 1$ , and  $\widetilde{p}_{128} = 0^{120}10000111$ . For n=64,  $p_n(x) = x^{64} + x^4 + x^3 + x + 1$ , and  $\widetilde{p}_{64} = 0^{59}11011$ .
- q number of blocks in the data string D after the padding and splitting process.
- S secret string of length (in bits) n.
- $S_1$ ,  $S_2$  secret strings of length (in bits)  $t \cdot n$ .
- t smallest integer greater than or equal to k/n.
- $j \sim X$  string obtained from the string X by taking the leftmost j bits of X.
- $X \oplus Y$  exclusive-or of bit-strings X and Y.
- X||Y concatenation of bit-strings X and Y (in that order).
- $0^n$  string consisting of *n* zero bits.
- symbol denoting the 'set equal to' operation, used in the procedural specifications of MAC algorithms, where it indicates that the value of the string on the left side of the symbol shall be made equal to the value of the expression on the right side of the symbol.
- finite field multiplication. In the polynomial representation, each element of  $GF(2^n)$  is represented by a binary polynomial of degree less than n. More explicitly the bit string  $A = a_{n-1} \dots a_2 a_1 a_0$  is mapped to the binary polynomial  $a(x) = a_{n-1} x^{n-1} + \dots + a_2 x_2 + a_1 x + a_0$ . Multiplication in the finite field  $GF(2^n)$ , denoted by A\*B, corresponds to the multiplication of two polynomials a(x)b(x) modulo a binary irreducible polynomial  $p_n(x)$  of degree n; that is, A\*B is the polynomial of degree at most n-1 obtained by multiplying a(x) and b(x), dividing the result by  $p_n(x)$ , and then taking the remainder. Here  $p_n(x)$  is chosen to be the lexicographically first polynomial from among the irreducible polynomials of degree n that have a minimum number of non-zero coefficients. For n=128,  $p_n(x) = x^{128} + x^7 + x^2 + x + 1$ .
- X << 1 string obtained from the string X by a left shift of 1 bit; if the length of X is n bits then X << 1 is the string consisting of the rightmost n bits of X || 0.

#### 5 Requirements

Users who wish to employ a MAC algorithm from this part of ISO/IEC 9797 shall select:

- a block cipher *e*, either one of those specified in ISO/IEC 18033-3 or the DEA block cipher (specified in Annex A of ISO/IEC 18033-3:2005 and ANSI X3.92 [10]). DEA may only be used with MAC Algorithms 3 and 4;
- a padding method from amongst those specified in 6.3;
- a MAC algorithm from amongst those specified in Clause 7;
- the length (in bits) *m* of the MAC; and
- a common key derivation method if MAC Algorithm 4 is used; a common key derivation method may also be required for MAC Algorithms 2 and 6.

Agreement on these choices amongst the users is essential for the purpose of the operation of the data integrity mechanism.

The length m of the MAC shall be a positive integer less than or equal to the block length n.

If Padding Method 3 is used, the length in bits of the data string D shall be less than  $2^n$ .

If MAC Algorithm 4 is used, the number of blocks in the padded version of the data string shall be greater than or equal to two, i.e.,  $q \ge 2$ .

The selection of a specific block cipher e, padding method, MAC algorithm, value for m, and key derivation method (if any) are beyond the scope of this part of ISO/IEC 9797.

NOTE 1 These choices affect the security level of the MAC algorithm. For a detailed discussion, see Annex C.

The same key shall be used for calculating and verifying the MAC. If the data string is also being encrypted, the key used for the calculation of the MAC shall be different from that used for encryption.

NOTE 2 It is considered to be good cryptographic practice to have independent keys for confidentiality and for data integrity.

The security of the MAC algorithms in this part of ISO/IEC 9797 is critically dependent on the procedures and practices followed to manage the keys. Information about key management can be found in ISO 8732 [3], ISO/IEC 11770 [8] and ISO 11568 [9].

Disclosure of intermediate values during the computation of the MAC algorithms may enable forgery and/or key recovery attacks (cf. Annex C).

#### 6 Model for MAC algorithms

#### 6.1 General

The application of the MAC algorithm requires the following seven steps: key derivation (optional), padding, splitting, iterative application of the block cipher, final iteration, output transformation, and truncation. Steps 4 through 7 are illustrated in Figure 1.

NOTE In MAC Algorithm 4, the first stage of the iteration (Step 4) is different from the other stages.

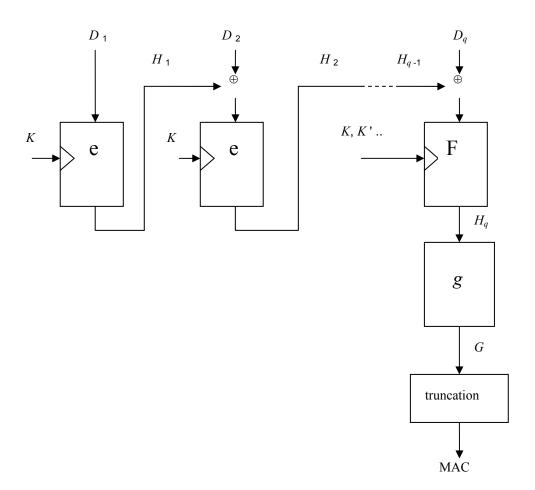

Figure 1 — Application of steps 4, 5, 6 and 7 of the MAC algorithm

#### 6.2 Step 1 (key derivation)

#### 6.2.1 General

MAC Algorithm 5 uses a key derivation algorithm which derives two masking keys from a block cipher key. MAC Algorithms 2, 4 and 6 may need a key derivation algorithm, which derives two block cipher keys from a block cipher key.

This part of ISO/IEC 9797 specifies two key derivation algorithms.

#### 6.2.2 Key Derivation Method 1

This key derivation method computes two block cipher keys K' and K'', each of length (in bits) k, from a block cipher key K.

This key derivation method uses the Counter Method (CTR) defined in ISO/IEC 10116 [7]. It consists of the following operations:

- Define the integer t as the smallest integer greater than or equal to  $k \ln n$ .
- Define the counter  $CT_i$ ,  $1 \le i \le 2t$  as the string consisting of the binary representation of the integer i left-padded with as few (possibly none) '0' bits as necessary to obtain an n-bit block.
- Compute the string  $S_1$  of length (in bits) tn equal to  $e_K(CT_1)||e_K(CT_2)||...||e_K(CT_t)|$  and set  $K' := k \sim S_1$ .
- Compute the string  $S_2$  of length (in bits) tn equal to  $e_K(CT_{t+1})||e_K(CT_{t+2})||...||e_K(CT_{2t})$  and set  $K'' := k \sim S_2$ .

#### 6.2.3 Key Derivation Method 2

This key derivation method computes two masking keys  $K_1$  and  $K_2$  of length in bits n from a block cipher key.

It consists of the following operations:

- First the secret string S of length in bits n is computed as follows:  $S := e_K(0^n)$ .
- Next the masking key  $K_1$  is obtained from  $S: K_1 := \text{multx}(S)$ .
- Finally the masking key  $K_2$  is derived from  $K_1$ :  $K_2$ := multx( $K_1$ ).

#### 6.3 Step 2 (padding)

#### 6.3.1 General

This step involves prefixing and/or postfixing the data string D with additional 'padding' bits such that the padded version of the data string will always be a multiple of n bits in length. The padding bits that are added to the original data string, according to the chosen padding method, are only used for calculating the MAC. Consequently, these padding bits (if any) need not be stored or transmitted with the data. The verifier shall know whether or not the padding bits have been stored or transmitted, and which padding method is in use.

This part of ISO/IEC 9797 specifies four padding methods. Padding methods 1, 2 and 3 can be chosen for MAC Algorithms 1, 2, 3, 4, and 6 specified in this part of ISO/IEC 9797. Padding method 4 shall only be used with MAC Algorithm 5.

#### 6.3.2 Padding Method 1

The data string D to be input to the MAC algorithm shall be right-padded with as few (possibly none) '0' bits as necessary to obtain a data string whose length (in bits) is a positive integer multiple of n.

NOTE 1 MAC algorithms using Padding Method 1 may be subject to trivial forgery attacks. See informative Annex C for further details.

NOTE 2 If the data string is empty, Padding Method 1 specifies that it is right-padded with n '0' bits.

#### 6.3.3 Padding Method 2

The data string D to be input to the MAC algorithm shall be right-padded with a single '1' bit. The resulting string shall then be right-padded with as few (possibly none) '0' bits as necessary to obtain a data string whose length (in bits) is a positive integer multiple of n.

NOTE If the data string is empty, Padding Method 2 specifies that it is right-padded with a single '1' bit followed by n - 1 '0' bits.

#### 6.3.4 Padding Method 3

The data string D to be input to the MAC algorithm shall be right-padded with as few (possibly none) '0' bits as necessary to obtain a data string whose length (in bits) is a positive integer multiple of n. The resulting string shall then be left-padded with a block L. The block L consists of the binary representation of the length (in bits)  $L_D$  of the unpadded data string D, left-padded with as few (possibly none) '0' bits as necessary to obtain an n-bit block. The right-most bit of the block L corresponds to the least significant bit of the binary representation of  $L_D$ .

NOTE 1 Padding Method 3 is not suitable for use in situations where the length of the data string is not available prior to the start of the MAC calculation.

NOTE 2 If the data string is empty, Padding Method 3 specifies that it is right-padded with n '0' bits and left-padded with a block L consisting of n '0' bits.

#### 6.3.5 Padding Method 4

If the data string D to be input to the MAC algorithm has a length (in bits) that is a positive integer multiple of n, no padding shall be applied. Otherwise, the data string D shall be right-padded with a single '1' bit. The resulting string shall then be right-padded with as few (possibly none) '0' bits as necessary to obtain a data string whose length (in bits) is a positive integer multiple of n.

NOTE If the data string is empty, Padding Method 4 specifies that it is right-padded with a single '1' bit followed by n - 1 '0' bits.

#### 6.4 Step 3 (splitting)

The padded version of the data string D is split into q n-bit blocks  $D_1, D_2, ..., D_q$ . Here  $D_1$  represents the first n bits of the padded version of D,  $D_2$  represents the next n bits, and so on.

#### 6.5 Step 4 (iteration)

The blocks  $H_1, H_2, ..., H_{q-1}$  are calculated by iteratively applying the block cipher with block cipher key K to the bitwise exclusive-or of the data block  $D_i$  and the previous result  $H_{i-1}$ :

$$H_0 := 0$$
;  
for  $i$  from 1 to  $q$  - 1:  
$$H_i := e_K(D_i \oplus H_{i-1});$$

If q is equal to 1, Step 4 shall be omitted.

NOTE This operation corresponds to CBC (Cipher Block Chaining) mode with starting variable fixed to  $0^n$ , as defined in ISO/IEC 10116 [7].

#### 6.6 Step 5 (final iteration)

#### 6.6.1 General

The final iteration F is applied to the last block  $D_q$  of the padded data string to derive the block  $H_q$ .

Each of the six MAC algorithms specified in this part of ISO/IEC 9797 uses one of three possible final iterations.

#### 6.6.2 Final iteration 1

This transformation uses the same block cipher key K as the iteration. The block  $H_q$  is computed by applying the block cipher with key K as follows:

$$H_q := e_K (D_q \oplus H_{q-1}).$$

#### 6.6.3 Final iteration 2

This transformation uses a block cipher key K', which is different from the block cipher key K used in the iteration. The block  $H_a$  is computed by applying the block cipher with key K' as follows:

$$H_q := e_{K'}(D_q \oplus H_{q-1}).$$

#### 6.6.4 Final iteration 3

This transformation uses the same block cipher key K as the iteration and two masking keys  $K_1$  and  $K_2$  of length n. The block  $H_q$  is computed by XORing to the input the key  $K_1$  or  $K_2$  depending on the padding operation, followed by an encryption with the block cipher key K.

Following Padding Method 4, if the data string to be input to the MAC algorithm had a length (in bits) that is a positive integer multiple of n then:

$$H_q := e_K (D_q \oplus H_{q-1} \oplus K_1),$$

else

$$H_q := e_K (D_q \oplus H_{q-1} \oplus K_2).$$

#### 6.7 Step 6 (output transformation)

#### 6.7.1 General

The output transformation g is applied to the value  $H_q$ , obtained as a result of Step 5.

This part of ISO/IEC 9797 specifies three output transformations.

#### 6.7.2 Output Transformation 1

This output transformation is the identity function, i.e.,

$$G := H_q$$
.

#### 6.7.3 Output Transformation 2

This output transformation consists of applying the block cipher with block cipher key K' to  $H_q$ , i.e.,

$$G := e_{K'}(H_q).$$

#### 6.7.4 Output Transformation 3

This output transformation consists of applying the block cipher (in decryption mode) with the key K' to  $H_q$ , followed by applying the block cipher with key K to the result of this operation, i.e.,

$$G := e_K(d_{K'}(H_q)).$$

#### 6.8 Step 7 (truncation)

The MAC of m bits is derived by taking the leftmost m bits of the block G, i.e.,

MAC := 
$$m \sim G$$
.

#### 7 MAC algorithms

#### 7.1 General

This part of ISO/IEC 9797 specifies six MAC algorithms. The final iteration and output transformation are specified in each case.

#### 7.2 MAC Algorithm 1

MAC Algorithm 1 uses Final Iteration 1 and Output Transformation 1. The MAC algorithm key consists of the block cipher key K. MAC Algorithm 1 is illustrated in Figure 2.

MAC Algorithm 1 may be used with Padding Method 1, 2 or 3 specified in 6.3.

NOTE 1 The choice of padding method affects the security of the MAC algorithm. See informative Annex C for further details.

NOTE 2 MAC Algorithm 1 is subject to XOR forgery attacks (see Annex C). As a result this algorithm should only be used where such attacks are infeasible, e.g. because message lengths are fixed.

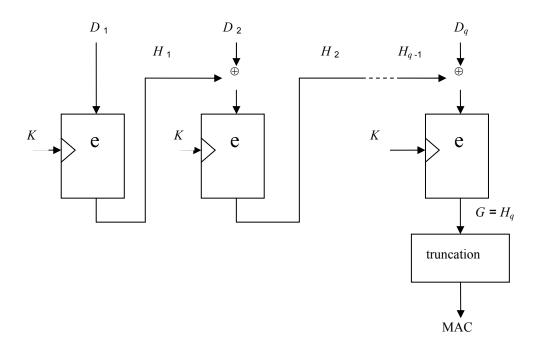

Figure 2 — MAC Algorithm 1

#### 7.3 MAC Algorithm 2

MAC Algorithm 2 uses Final Iteration 1 and Output Transformation 2. The MAC algorithm key consists of two block cipher keys K and K'. The values of K and K' may be derived from a common master key (a block cipher key) in such a way that K and K' are different with very high probability.

- NOTE 1 MAC Algorithm 2 is commonly known as EMAC [24].
- NOTE 2 An example of how to derive K and K' from a common master key is Key Derivation Method 1.
- NOTE 3 If K and K' are equal, a simple XOR forgery attack applies. See informative Annex C for further details.
- NOTE 4 If K and K' are independent, the level of security against key recovery attacks is less than suggested by the MAC algorithm key size. See informative Annex C for further details.

MAC Algorithm 2 is illustrated in Figure 3.

MAC Algorithm 2 may be used with Padding Method 1, 2 or 3 specified in 6.3.

NOTE 5 The choice of padding method affects the security of the MAC algorithm. See informative Annex C for further details.

NOTE 6 If MAC Algorithm 2 is used in combination with an algorithm that computes a (public) key identifier as  $S=e_K(0^n)$ , such as X9.24 [13], then MAC Algorithm 2 is subject to XOR forgery attacks (see Annex C). In this case the algorithm should only be used where such attacks are infeasible, e.g. because message lengths are fixed.

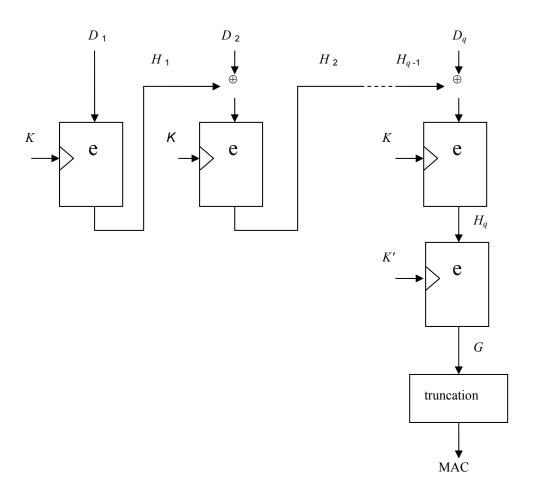

Figure 3 — MAC Algorithm 2

#### 7.4 MAC Algorithm 3

MAC Algorithm 3 uses Final Iteration 1 and Output Transformation 3. The MAC algorithm key consists of two block cipher keys K and K'. The values of K and K' shall be chosen independently. If K' = K, MAC Algorithm 3 reduces to MAC Algorithm 1. MAC Algorithm 3 is illustrated in Figure 4.

NOTE 1 MAC Algorithm 3 is commonly known as the ANSI retail MAC [12]. When MAC Algorithm 3 is used with DEA (specified in Annex A of ISO/IEC 18033-3:2005 and ANSI X3.92 [10]), the block cipher key length is 56 bits, while the key length is equal to 112 bits.

MAC Algorithm 3 may be used with Padding Method 1, 2 or 3 specified in 6.3.

NOTE 2 The choice of padding method affects the security of the MAC algorithm. See informative Annex C for further details.

NOTE 3 If MAC Algorithm 3 is used in combination with an algorithm that computes a (public) key identifier as  $S=e_K(0^n)$ , such as X9.24 [13], then MAC Algorithm 3 is subject to XOR forgery attacks (see Annex C). In this case the algorithm should only be used where such attacks are infeasible, e.g. because message lengths are fixed.

MAC Algorithm 3 should not be used in new applications because it was designed for use with an outdated cryptographic primitive.

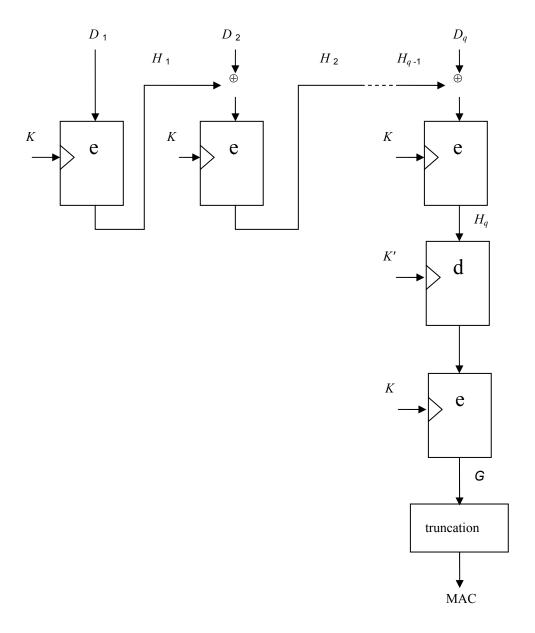

Figure 4 — MAC Algorithm 3

#### 7.5 MAC Algorithm 4

MAC Algorithm 4 uses Final Iteration 1 and Output Transformation 2. In addition, MAC Algorithm 4 changes the processing of the first block.

NOTE 1 When used with DEA (specified in Annex A of ISO/IEC 18033-3:2005 and ANSI X3.92 [10]), MAC Algorithm 4 is known as MacDES [21]. In this case, the block cipher key length is 56 bits, while the key length is equal to 112 bits.

The MAC algorithm key consists of two block cipher keys K and K', that shall be chosen independently. The third block cipher key K'' shall be derived from K'. The values of K, K', and K'' shall be different. The block cipher keys K and K'' are used in the processing of the first block, and the block cipher keys K and K' are used with Output Transformation 2.

NOTE 2 An example of how to derive K'' from K' is to complement alternate substrings of four bits of K' commencing with the first four bits. Another example is to derive both K' and K'' from a common master key as specified in Key Derivation Method 1.

The first block is not processed using the normal iteration (with one encryption) but rather using the following equation (with two encryptions):

$$H_1 := e_{K''} (e_K (D_1))$$
.

MAC Algorithm 4 is illustrated in Figure 5.

MAC Algorithm 4 may be used with Padding Method 1, 2 or 3 specified in 6.3.

NOTE 3 The choice of padding method affects the security of the MAC algorithm. See informative Annex C for further details.

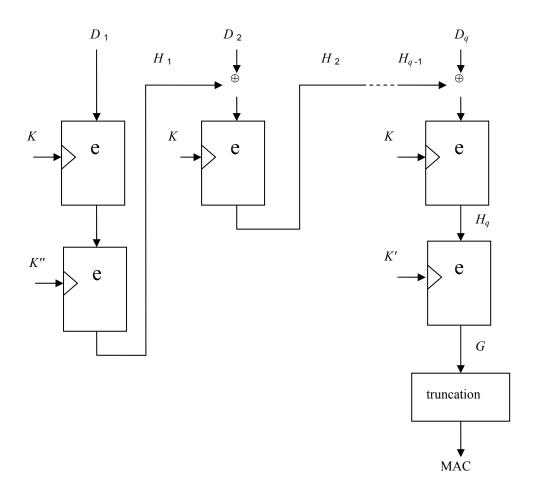

Figure 5 — MAC Algorithm 4

#### 7.6 MAC Algorithm 5

MAC Algorithm 5 uses Key Derivation Method 2, Final Iteration 3 and Output Transformation 1. MAC Algorithm 5 shall only be used with Padding Method 4. The masking keys  $K_1$  and  $K_2$  to be used in Final Iteration 3 are derived from the MAC algorithm key K using Key Derivation Method 2.

NOTE 1 MAC Algorithm 5 is commonly known as OMAC1 [19] or CMAC [14].

The MAC algorithm key consists of a single block cipher key *K*.

MAC Algorithm 5 is illustrated in Figure 6, in which  $K_i = K_1$  or  $K_2$ .

NOTE 2 If MAC Algorithm 5 is used in combination with an algorithm that computes a (public) key identifier as  $S=e_K(0^n)$ , such as X9.24 [13], then MAC Algorithm 5 is subject to XOR forgery attacks (see Annex C). In this case the algorithm should only be used where such attacks are infeasible, e.g. because message lengths are fixed.

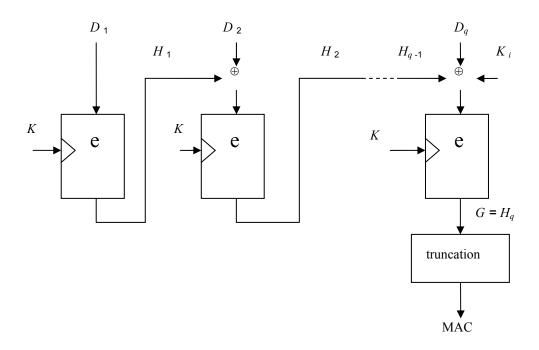

Figure 6 — MAC Algorithm 5

#### 7.7 MAC Algorithm 6

MAC Algorithm 6 uses Final Iteration 2 and Output Transformation 1. The MAC algorithm key consists of two block cipher keys K and K'. The values of K and K' may be derived from a common master key (a block cipher key) in such a way that K and K' are different with very high probability.

- NOTE 1 MAC Algorithm 6 is commonly known as LMAC.
- NOTE 2 An example of how to derive K and K' from a common master key is Key Derivation Method 1.
- NOTE 3 If K and K' are equal, a simple XOR forgery attack applies. See informative Annex C for further details.
- NOTE 4 If K and K' are independent, the level of security against key recovery attacks is less than suggested by the MAC algorithm key size. See informative Annex C for further details.
- MAC Algorithm 6 is illustrated in Figure 7.
- MAC Algorithm 6 may be used with Padding Method 1, 2 or 3 specified in 6.3.
- NOTE 5 The choice of padding method affects the security of the MAC algorithm. See informative Annex C for further details.
- NOTE 6 If MAC Algorithm 6 is used in combination with an algorithm that computes a (public) key identifier as  $S=e_K(0^n)$ , such as X9.24 [13], then MAC Algorithm 6 is subject to XOR forgery attacks (see Annex C). In this case the algorithm should only be used where such attacks are infeasible, e.g. because message lengths are fixed.

# Annex B (informative)

### **Examples**

#### **B.1 General**

This annex presents examples of the generation of a MAC.

For MAC Algorithms 1–4, the plaintexts are the 7-bit ASCII codes (no parity) for data string 1: "Now $\Box$ is $\Box$ the $\Box$ time $\Box$ for $\Box$ all $\Box$ " and data string 2: "Now $\Box$ is $\Box$ the $\Box$ time $\Box$ for $\Box$ it", where " $\Box$ " denotes a blank. ASCII coding is equivalent to coding using ISO 646. All MAC values and key values are written in hexadecimal notation.

For data string 1, the results of applying padding methods 1–3 are as follows:

— Padding Method 1: q = 3

$D_1$	4E	6F	77	20	69	73	20	74
$D_2$	68	65	20	74	69	6D	65	20
$D_3$	66	6F	72	20	61	6C	6C	20

— Padding Method 2: q = 4

$D_1$	4E	6F	77	20	69	73	20	74
$D_2$	68	65	20	74	69	6D	65	20
$D_3$	66	6F	72	20	61	6C	6C	20
$D_4$	80	00	00	00	00	00	00	00

— Padding Method 3: q = 4

$D_1$	00	00	00	00	00	00	00	C0
$D_2$	4E	6F	77	20	69	73	20	74
$D_3$	68	65	20	74	69	6D	65	20
$D_4$	66	6F	72	20	61	6C	6C	20

For data string 2, the results of applying padding methods 1–3 are as follows:

— Padding Method 1: q = 3

$D_1$	4E	6F	77	20	69	73	20	74
$D_2$	68	65	20	74	69	6D	65	20
$D_3$	66	6F	72	20	69	74	00	00

#### ISO/IEC 9797-1:2011(E)

#### — Padding Method 2: q = 3

$D_1$	4E	6F	77	20	69	73	20	74
$D_2$	68	65	20	74	69	6D	65	20
$D_3$	66	6F	72	20	69	74	80	00

#### — Padding Method 3: q = 4

$D_1$	00	00	00	00	00	00	00	в0
$D_2$	4E	6F	77	20	69	73	20	74
$D_3$	68	65	20	74	69	6D	65	20
$D_4$	66	6F	72	20	69	74	00	00

## **B.2 MAC Algorithm 1**

The examples given use DEA as the block cipher (specified in Annex A of ISO/IEC 18033-3:2005 and ANSI X3.92 [10]). The key value used is K = 0123456789 ABCDEF (hexadecimal). The length m in bits of the MAC is equal to 32.

### **B.3 MAC Algorithm 2**

The examples given use DEA as the block cipher (specified in Annex A of ISO/IEC 18033-3:2005 and ANSI X3.92 [10]). The two key values used are K = 0123456789 ABCDEF (hexadecimal), and K' is computed by complementing alternate substrings of four bits commencing with the first four bits. The length m in bits of the MAC is equal to 32.

The first q steps are identical to those of MAC Algorithm 1. The only difference is that Output Transformation 2 is applied instead of Output Transformation 1.

#### **B.6 MAC Algorithm 5**

#### **B.6.1 Examples of MAC generation process**

Ten examples of the MAC generation process for this algorithm are provided. The underlying block cipher in these examples is either AES or triple DEA (TDEA) (both of which are specified in ISO/IEC 18033-3:2005).

Two examples are provided for each of the possible key lengths for these two ciphers, i.e. 128, 196 and 256 bits for AES, and two-key and three-key TDEA. Within each pair of examples, the MAC computation for two different messages is given, both using the same key. The generation of masking keys  $K_1$  and  $K_2$  from the key K is specified in each case, followed by the two examples of MAC generation.

All strings are represented in hexadecimal notation.

#### B.6.2 AES using a 128-bit key

The following 128-bit key and associated derived masking keys are used in both examples:

key (K)	2B	7E	15	16	28	AE	D2	A6	AB	F7	15	88	09	CF	4F	3C

## **B.7 MAC Algorithm 6**

## **B.7.1 Examples of MAC generation process**

Three examples of the MAC generation process for this algorithm are provided. The underlying block cipher in these examples is AES (specified in ISO/IEC 18033-3:2005). Padding Method 2 is used.

One example is provided for each possible key length for this cipher, i.e. 128, 196 and 256 bits. The generation of K and K' from a single key  $K^*$  is specified in each case, followed by the example of MAC generation.

All strings are represented in hexadecimal notation.

## B.7.2 AES using a 128-bit key

The following keys K and K' are used in the example (where K and K' are derived from  $K^*$  using key derivation method 1):

K*	91	18	69	5B	E6	В7	86	F2	81	7A	BE	FB	54	E2	58	29

ISO/IEC 9797-1:2011(E)

# Annex C (informative)

## A security analysis of the MAC algorithms

## C.1 General

This Annex discusses the security level of the MAC algorithms in this part of ISO/IEC 9797. Its goal is to assist the user of this part of ISO/IEC 9797 in selecting one of the mechanisms.

It will be assumed that the key length of the block cipher is k bits, while the key length of the MAC algorithm is equal to  $k^*$  bits. The value of  $k^*$  is thus equal to k or to 2k.

In this Annex,  $MAC_K(D)$  denotes the MAC for a string D computed using the MAC algorithm key K.

In order to determine the security level of a MAC algorithm, two attack strategies are considered:

- forgery attack: This attack consists of predicting the value of  $MAC_K(D)$  for a data string D without initial knowledge of K. If the adversary can do this for a single data string, he is said to be capable of a *forgery*. Practical attacks often require that a forgery is *verifiable*, i.e., that the forged MAC is known to be correct beforehand with probability near 1. Moreover, in many applications the data string has a specific format, which imposes additional constraints on the data string D.
- key recovery attack: This attack consists of finding the MAC algorithm key K itself from a number of data string/MAC pairs. Such an attack is more powerful than forgery, since it allows for arbitrary forgeries. Note that a key length of 56 bits (as of the DEA algorithm) is no longer considered to offer sufficient protection for most applications.

The feasibility of an attack depends on the number of known and chosen data string/MAC pairs required, and on the number of off-line encryptions.

Possible attacks against MAC algorithms are described below; there is no guarantee that this list is exhaustive. The first two attacks are generic, i.e., they apply to any MAC algorithm. The next attack applies to any iterated MAC algorithm. The following three attacks are specific to one or more of the MAC algorithms described in this part of ISO/IEC 9797 (for more details see [15], [20], [21], [25], [26], [27]).

- **guessing the MAC**: This is a forgery which is not verifiable, and which has a success probability of  $\max(1/2^m, 1/2^{k^*})$ . This attack applies to all MAC algorithms, and can only be precluded by a judicious choice of m and  $k^*$ .
- brute force key recovery: This attack should require on average  $2^{k^*-1}$  operations; verification of such an attack requires of the order of  $k^*/m$  data string/MAC pairs. Again this attack applies to all MAC algorithms. It can be precluded by a judicious choice of the value  $k^*$ . Alternatively, one can prevent someone obtaining the  $k^*/m$  data string/MAC pairs which are necessary to identify the key uniquely. For example, if  $k^* = 64$  and m = 32, approximately  $2^{32}$  keys correspond to a given data string/MAC pair; if the key is changed after every data string, a brute force key recovery is no more effective than guessing the MAC value.
- birthday forgery [25], [27]: If one collects approximately  $2^{n/2}$  data string/MAC pairs, this set will contain with high probability two data strings D and D' such that  $\mathsf{MAC}_K(D) = \mathsf{MAC}_K(D')$  and the values of  $H_q$  in both computations are equal; this is called an internal collision. If D and D' form an internal collision,  $\mathsf{MAC}_K(D||Y) = \mathsf{MAC}_K(D'||Y)$  for any string Y. This allows for a forgery after one chosen data string, as an adversary can predict the MAC for D'||Y after having observed the MAC corresponding to D||Y. This

forgery is again on data strings of a specific form, which may not be a concern in all applications, but it should be noted that extensions of this attack exist which allow for greater flexibility in the data strings. The attack requires one chosen data string, and approximately  $2^{n/2}$  known data strings and min $\{2^{n-m}, 2^{n/2}\}$  chosen data strings.

Note that the birthday forgery attack cannot be precluded by the combination of Padding Method 3 and the prepending of a block to the data string which contains a serial number (see [16] for more details).

- trivial forgery: If Padding Method 1 is used, an adversary can typically add or delete a number of trailing '0' bits of the data string without changing the MAC. This implies that Padding Method 1 shall only be used in environments where the length of the data string D is known to the parties beforehand, or where data strings with a different number of trailing '0' bits have the same semantics.
- **XOR forgery**: If MAC Algorithm 1 is used with Padding Method 1 or 2 and m = n, a simple XOR forgery is possible. Assume, for simplicity, that D has the property that its padded version  $\overline{D}$  consists of a single block (hence, if Padding Method 2 is used, we are assuming that D is of length less than n bits). In addition let v denote the mapping that removes from a bit string the rightmost one, and all the zeros that follow this bit (and hence if  $\overline{v(X)}$  denotes the padded version of v(X) using Padding Method 2, then  $\overline{v(X)} = X$ ).

Assume that one knows  $MAC_K(D)$ . If Padding Method 1 is used then it follows immediately that  $MAC_K(\overline{D} \mid | (\overline{D} \oplus MAC_K(D))) = MAC_K(D)$ . Similarly, if Padding Method 2 is used, then it follows that  $MAC_K(\overline{D} \mid | v(\overline{D} \oplus MAC_K(D))) = MAC_K(D)$ . This implies that one can construct a new message with the same MAC value, which is a forgery.

Note that this attack applies even if a MAC algorithm key is used only once. Assume that one knows  $MAC_K(D)$  and  $MAC_K(D')$ . If Padding Method 1 is used, then a similar calculation shows that  $MAC(\overline{D} || \overline{D'} \oplus MAC_K(D))) = MAC_K(D')$  (here D can be of arbitrary length but D' must be one block long). Similarly, if Padding Method 2 is used, then it follows that  $MAC(\overline{D} || v(\overline{D'} \oplus MAC_K(D))) = MAC_K(D')$  (here D can be of arbitrary length but  $\overline{D'}$  must be one block long).

Additionally, for Padding Method 1, if one knows  $MAC_K(D)$ ,  $MAC_K(D||Y)$ , and  $MAC_K(D')$ , one knows that  $MAC_K(D'||Y') = MAC_K(D||Y)$  if  $Y' = Y \oplus MAC_K(D) \oplus MAC_K(D')$  (if D and Y fall on block boundaries). This also allows for a forgery, as an adversary can forge the MAC on D' || Y' given knowledge of the MACs for two known data strings and one chosen data string. A similar (but slightly more complex) forgery attack also works for Padding Method 2.

Note that all the above forgeries are on data strings of a specific form, which may not be a concern in all applications.

This attack can be precluded by using Padding Method 3.

This attack can be extended to the case m < n, but it becomes more difficult: in that case it requires knowledge of the MACs for an additional  $2^{(n-m)/2}$  chosen data strings [20].

The same attack applies when MAC Algorithm 2 is used with two equal keys, i.e., K'=K. In this case the attack works when Y contains at least two blocks, and the first N bits of Y are '0' bits.

— shortcut key recovery: Some MAC algorithms are potentially vulnerable to key recovery attacks based on an internal collision. Examples are MAC Algorithm 3 (see [21], [22], [26]) and MAC Algorithm 4 in combination with Padding Method 1 or 2 [18] or Padding Method 3 [17]. MAC Algorithm 5 allows for a partial key recovery attack [23]; once part of the key has been obtained, finding forgeries becomes easy.

The following tables present a comparison of the security level of the MAC algorithms described in this part of ISO/IEC 9797. It is assumed that the block cipher has no weaknesses. Table C.1 indicates the main properties of the MAC algorithms. As Padding Method 1 allows for a trivial forgery, the comparison involving MAC Algorithms 1, 2, 3, 4 and 6 considers only Padding Methods 2 and 3. Tables C.2 and C.3 present the

best known attacks for block ciphers with n=64 and k=56 (e.g., the Data Encryption Algorithm [10]). Table C.6 and C.7 are for block ciphers with n=64 and k=128; Tables C.4 and C.5 are for block ciphers with n=128 and k=128. In these cases only MAC Algorithms 1 and 2 are considered, as there is no need to double the key length of the MAC algorithm. The description of these attacks can be found in [15], [16], [17], [18], [19], [20], [21], [25], [26], [27]. An attack is described as a four-tuple  $[\alpha, \beta, \gamma, \delta]$ , where  $\alpha$  denotes the number of off-line block cipher encryptions,  $\beta$  denotes the number of known data string/MAC pairs,  $\gamma$  denotes the number of chosen data string/MAC pairs, and  $\delta$  denotes the number of on-line MAC verifications.

In [15], [24], a lower bound is proved on the security level of the basic CBC-MAC construction (MAC Algorithm 1) based on certain properties of the block cipher. This suggests that many of the birthday attacks discussed are close to the best attacks possible provided that the block cipher is strong. Reference [24] provides a security argument for MAC Algorithm 2.

### C.2 Rationale

This clause explains the selection of the MAC algorithms in this part of ISO/IEC 9797. An important factor in the selection of the proposed mechanism has been to maintain backward compatibility with the previous ANSI, ISO, and ISO/IEC standards, with the exception of MAC Algorithms 5 and 6 from ISO/IEC 9797-1:1999, which have been removed. The motivation for this removal is that the additional security offered is lower than anticipated.

MAC Algorithm 4 provides an improved way of increasing the key length compared to MAC Algorithm 3. It is *strongly recommended* to use this algorithm in combination with Padding Method 3; in that case it provides better security than MAC Algorithm 3 for the same cost.

MAC Output number Final It. **Padding** #Keys efficiency Algorithm Transf. 1.1 1 1 1 t+1 1.2 1 1 1 3 1 t+2 2 2.1 1 2 2 1 t+2 2 2.2 2 1 2 2 t+2 2 2 3 3 1 3 t+3 2 4 2 2 4.1 1 t+3 2 4.2 4 3 2 t+4 1 1† 5 3 4 t† 5 1 6 2 1 2 6.1 1 t+1 6.2 6 2 1 2 2 t+1

Table C.1 — Properties of MAC algorithms

#Keys denotes the number of independent block cipher keys. The efficiency denotes the number of encryptions to process a data string of tn bits.

 $<sup>^{\</sup>dagger}$  MAC Algorithm 5 needs a precomputation of one encryption and needs storage of two extra n-bit keys.

<sup>†</sup> Can be precluded by prepending a serial number to the data string in combination with Padding Method 3

<sup>‡</sup> Recovers only the masking keys which allows for trivial forgeries

<sup>‡</sup> Recovers only the masking keys which allows for trivial forgeries

ISO/IEC 9797-1:2011(E)

# **Annex D** (informative)

## A comparison with previous MAC algorithm standards

This Annex compares the MAC algorithms in this part of ISO/IEC 9797 with earlier MAC algorithm standards.

The calculation of a MAC as described in ISO 8731-1 and ANSI X9.9 is a specific case of this part of ISO/IEC 9797 when n = 64, m = 32, MAC Algorithm 1 and Padding Method 1 are used, and the block cipher is DEA (ANSI X3.92:1981). The calculation of a MAC as described in ANSI X9.19 and ISO 9807 is a specific case of this part of ISO/IEC 9797 when n = 64, m = 32, either MAC Algorithm 1 or MAC Algorithm 3 is used (both with Padding Method 1), and the block cipher is DEA (ANSI X3.92:1981).

# British Standards Institution (BSI)

BSI is the national body responsible for preparing British Standards and other standards-related publications, information and services.

BSI is incorporated by Royal Charter. British Standards and other standardization products are published by BSI Standards Limited.

### About us

We bring together business, industry, government, consumers, innovators and others to shape their combined experience and expertise into standards

The knowledge embodied in our standards has been carefully assembled in a dependable format and refined through our open consultation process. Organizations of all sizes and across all sectors choose standards to help them achieve their goals

### Information on standards

We can provide you with the knowledge that your organization needs to succeed. Find out more about British Standards by visiting our website at bsigroup.com/standards or contacting our Customer Services team or Knowledge Centre.

## **Buying standards**

You can buy and download PDF versions of BSI publications, including British and adopted European and international standards, through our website at bsigroup. com/shop, where hard copies can also be purchased.

If you need international and foreign standards from other Standards Development Organizations, hard copies can be ordered from our Customer Services team.

## Copyright in BSI publications

All the content in BSI publications, including British Standards, is the property of and copyrighted by BSI or some person or entity that owns copyright in the information used (such as the international standardization bodies) and has formally licensed such information to BSI for commercial publication and use.

Save for the provisions below, you may not transfer, share or disseminate any portion of the standard to any other person. You may not adapt, distribute, commercially exploit or publicly display the standard or any portion thereof in any manner whatsoever without BSI's prior written consent.

## Storing and using standards

Standards purchased in soft copy format:

- A British Standard purchased in soft copy format is licensed to a sole named user for personal or internal company use only.
- The standard may be stored on more than one device provided that it is accessible by the sole named user only and that only one copy is accessed at
- A single paper copy may be printed for personal or internal company use only.

Standards purchased in hard copy format:

- A British Standard purchased in hard copy format is for personal or internal company use only.
- It may not be further reproduced in any format to create an additional copy. This includes scanning of the document

If you need more than one copy of the document, or if you wish to share the document on an internal network, you can save money by choosing a subscription product (see 'Subscriptions').

## Reproducing extracts

For permission to reproduce content from BSI publications contact the BSI Copyright and Licensing team.

## Subscriptions

Our range of subscription services are designed to make using standards easier for you. For further information on our subscription products go to bsigroup.

With British Standards Online (BSOL) you'll have instant access to over 55,000 British and adopted European and international standards from your desktop. It's available 24/7 and is refreshed daily so you'll always be up to date.

You can keep in touch with standards developments and receive substantial discounts on the purchase price of standards, both in single copy and subscription format, by becoming a BSI Subscribing Member.

PLUS is an updating service exclusive to BSI Subscribing Members. You will automatically receive the latest hard copy of your standards when they're revised or replaced

To find out more about becoming a BSI Subscribing Member and the benefits of membership, please visit bsigroup.com/shop

With a Multi-User Network Licence (MUNL) you are able to host standards publications on your intranet. Licences can cover as few or as many users as you wish. With updates supplied as soon as they're available, you can be sure your documentation is current. For further information, email cservices@bsigroup.com.

Our British Standards and other publications are updated by amendment or revision.

We continually improve the quality of our products and services to benefit your business. If you find an inaccuracy or ambiguity within a British Standard or other BSI publication please inform the Knowledge Centre.
